

Grange Farm Energy Biomethane Plant CO₂ Analysis Report

August 2018

Grange Farm Energy Biomethane Plant

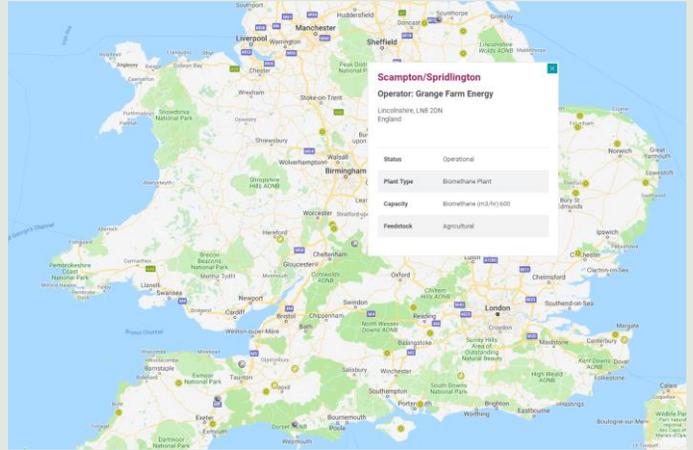

CO₂ Analysis Report

Executive Summary

Aardvark Certification Ltd (ACL) has been instructed by John Laing Environmental Assets Group Ltd to assess and report against the carbon savings achieved by the 600m³/hr Grange Farm Energy Biomethane Plant located at Grange Farm, Lincolnshire, LN8 2DN. This assessment considers the CO₂ savings made as a result of this biogas plant as well as the wider environmental benefits the project has delivered.

Asset Introduction

The Grange Farm Energy Biomethane Plant is fed on a menu of 42,000 tonnes per annum of agricultural feedstocks including whole crop maize, rye, sugar beet and grass silage. The biogas plant has a designed export capacity of 450m³/hr biomethane with all biomethane produced exported directly to the national gas grid. A small CHP provides heat and power to meet the energy requirements of the plant with surplus electricity exported to the grid. The plant was commissioned in December 2014 and to date has produced 16,654MWh of renewable electricity and a further 146,272MWh of biomethane.

CO₂ Savings from Biomethane

Biomethane offsets significant CO₂ emissions compared with fossil fuel derived gas and electricity. Standard conversion factors for fossil fuel derived electricity, natural gas and biomethane are shown below:
 UK Generated Electricity: 0.28037 kg CO₂e per kWh
 Natural Gas: 0.18396 kg CO₂e per kWh (gross CV)
 Biomethane: 0.00037703 kg CO₂e per kWh (gross CV)
 The calculated CO₂ savings shown within this report are based on the actual savings achieved by the site.

Greenhouse Gas Emissions

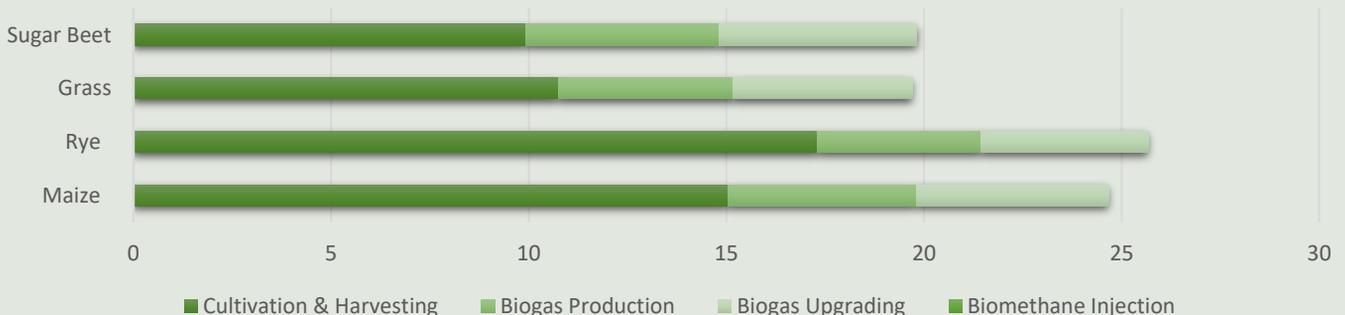

The Grange Farm Biomethane Plant uses a range of agricultural feedstocks to produce energy which comprise of purpose grown crops. The cultivation, harvesting and conversion of the crops to energy requires an element of fossil fuel use. The actual CO₂ savings achieved therefore need to account for the associated GHG emissions produced through the use of the crop based feedstocks. A simplified illustration of the fuel chain shows each step at which GHG emissions are produced through use of crop based feedstocks.

GHG Emissions by Feedstock

Each crop based feedstock has been assessed to determine the specific GHG emissions associated with their use with emissions at each step in the fuel chain quantified and shown below:

GHG Emissions per Feedstock (gCO₂e/MJ biomethane)

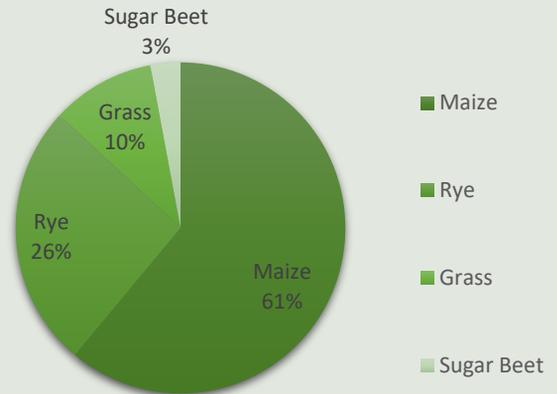

Grange Farm Energy Biomethane Plant

CO₂ Analysis Report

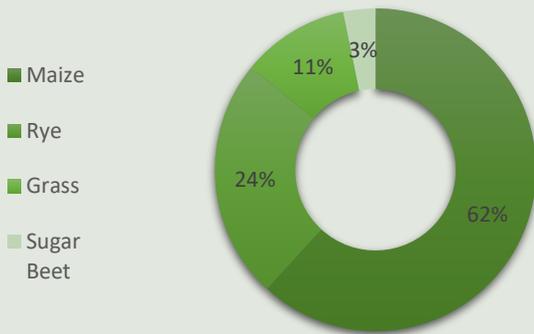

Biogas Apportioning

As the Grange Farm Biomethane Plant uses a range of agricultural feedstocks, it is necessary to understand what proportion of the biogas produced is derived from each feedstock in order to quantify the CO₂ savings achieved by the plant. To do this we apportion the biogas across the range of feedstocks based on their individual biogas yields.

Biogas Apportioned by Feedstock

CO₂ saved by Feedstock

CO₂ Apportioning

In order to account for the associated GHG emissions resulting from the use of purpose grown crops to produce the electricity and biomethane, it is necessary to apportion the CO₂ emissions saved as a result of the operation of the biomethane plant by feedstock type. This shows that whilst some feedstocks contribute more to overall biogas production than others, these are not necessarily delivering the highest levels of CO₂ savings for the plant as emissions associated with their production can be greater.

CO₂ Savings

With the preceding analysis, it is possible to calculate the CO₂ savings the plant has achieved over its lifetime had the equivalent quantity of energy been derived from fossil fuel sources. Total CO₂ emissions which would have come from an equivalent quantity of electricity or natural gas from fossil fuel sources in the UK is shown below along with CO₂ savings made through energy production from the biomethane plant. This shows a total saving to date of 3,876tCO₂e has been saved by the Grange Farm Biomethane Plant through its electricity export and a further 13,821tCO₂e has been saved through biomethane production.

Total Energy Produced			UK Generated Electricity	Biogas Generated Electricity
Electricity	16,654	MWh	0.28088	
			4,677,837	802,257
			3,875,581	
Total Energy Produced			UK Natural Gas Emissions	Biomethane Emissions
Biomethane	146,272	MWh	0.18396	
			26,908,282	13,087,187
			13,821,096	

CO₂ Forecast

An anaerobic digestion plant is typically designed with a 20 year operational lifetime. In practice this may go on well beyond the planned 20 years. Based on the expected 20 year operational forecast, the Grange Farm plant is expected to save a total of 88,483tCO₂e. This forecast is based on the current GHG emissions associated with the production of feedstocks and operation of the plant. In practice it is expected that improved technology and efficiencies over the remainder of the lifetime of the plant will enable it to reduce its own emissions thereby increasing the overall CO₂ savings it contributes.

Grange Farm Energy Biomethane Plant

CO₂ Analysis Report

What do these savings mean?

The CO₂ savings achieved by the project can be difficult to comprehend and relate to real world understanding. We therefore equate the savings to every day scenarios such as vehicles, and homes to assist readers in interpreting the data.

The Grange Farm Biomethane Plant has to date offset 17,697tCO₂e since commissioning and is expected to offset at least 88,483tCO₂e over its operational lifetime. This equates to:

- Equivalent emissions produced by a mid-sized diesel car driving around Earth's equator 12,723 times over the lifetime of the plant
- Removing 40,620 mid-sized diesel cars from UK roads based on the lifetime CO₂ savings the plant will achieve whilst it has already offset equivalent emissions to 8,124 cars.
- Providing enough gas for heating and cooking in 3,047 average UK homes over the lifetime of the plant
- Providing enough renewable electricity to power 1,343 average UK homes over the lifetime of the plant

Other Environmental Benefits

The Grange Farm Biomethane Plant delivers another important environmental benefit to the local farms around the plant through provision of a natural biofertilizer they are able to use. This offsets the need for fossil fuel derived fertilisers. The liquid fraction of the digestate has been particularly useful for establishment of cover crop, oilseed rape and grass. Use of the digestate as a direct replacement for traditional fertilisers offsets an estimated 472 t CO₂e per annum

Methodology

This report has been prepared in good faith by Aardvark Certification Ltd based on data obtained from the owner/operator of the asset reviewed. Our calculations of GHG emissions associated with the production of biogas from the plant has been through the Ricardo Biomethane and Heat GHG Calculator Tool, v 1.1 updated on 09/06/2016. Our GHG emissions assumptions for this plant are based on an annualised average emissions value for the plant by feedstock type. Biogas yield data is an average of the UKAS accredited laboratory analysis undertaken of the plants specific feedstocks over a three year period.

Our calculations of CO₂ savings are based on IFI Approach to GHG Accounting for Renewable Energy Projects. Baseline Emission Factors used in this analysis are taken directly from the Department for Business, Energy & Industrial Strategy Greenhouse gas reporting: conversion factors 2018.

Energy usage statistics are taken from OfGEM - <https://www.ofgem.gov.uk/gas/retail-market/monitoring-data-and-statistics/typical-domestic-consumption-values>

Mileage travelled per vehicle in the UK was taken from the RAC Foundation.

Digestate NPK values sourced from Defra's Fertiliser Manual 2017 (RB209) 9th edition
